Supplementary material S1. Light intensity experiment lighting Supplementary material S2. Press vs Pulse experiment lighting Supplementary material S3. Detailed PERMANOVA results Supplementary material S4. Photosynthetic pigments

## Supplementary material S1

Light intensity experiment lighting

Figure S1. Experimental tanks (a) and mean ( $\pm$ SE) total daily photon flux density (mol photons $\mathrm{m}^{-2}$ day $^{-1}$ ) in ambient, low, critical, and blackout treatments of the light intensity experiment ( b ; $\mathrm{n}=30$ for each bar).

## Supplementary material S2

## Press vs Pulse experiment lighting

Total daily PFD ranged from 0.8 to 9.2 mol photons $\mathrm{m}^{-2}$ day $^{-1}$ in ambient tanks and 0.4 to 3.5 mol photons $\mathrm{m}^{-2}$ day ${ }^{-1}$ in press (chronic low-light) tanks. For the first two days of the seven day light cycles, pulse tanks were close to complete darkness ( 0.02 to 0.65 mol photons $\mathrm{m}^{-2}$ day ${ }^{-1}$ ). Light slowly increased over days three to five and were comparable to ambient tanks for days six and seven ( $1.1-7.2 \mathrm{~mol}$ photons $\mathrm{m}^{-2} \mathrm{day}^{-1}$ ) (Fig. S2a). Total weekly PFD was significantly higher (c. 2 times greater) in ambient tanks than press and pulse tanks (Factor $=$ Treatment, $\mathrm{F}_{2,45}=139.34, p<0.0001$ ) but was similar between press and pulse tanks (LS means, $p=0.19$ ) (Fig. S2b). Total weekly PFD in ambient tanks was $c .9 .7 \%$ of surface irradiance, while press and pulse were only c. 4.0 and $4.1 \%$ of surface irradiance, respectively.

Figure S2. Mean ( $\pm$ SE) total daily photon flux density (mol photons $\mathrm{m}^{-2}$ day $^{-1}$ ) (a) and total weekly photon flux density (mol photons $\mathrm{m}^{-2}$ week ${ }^{-1}$ ) (b) in ambient, press, and pulse treatments of the press vs pulse experiment. Each point in (a) represents the average of four days for each of four tanks in each treatment ( $\mathrm{n}=16$ ). Each bar in (b) represents the average PFD of the four light cycles (one week) for each treatment ( $\mathrm{n}=4$ ). Bars not sharing the same letter are different (LS means tests, $p<0.05$ ).

## Supplementary material S3

Detailed PERMANOVA results
Initial parameters:
Table S3.1. Summary of ANOVAs (applied to normalized data using Type III SSs and 9999 permutations) ) examining differences of initial lamina biomass and photosynthetic parameters between species (fixed effect: E. radiata and C. flexuosum) and among light treatments (fixed effect: ambient, low, critical, blackout [light intensity experiment] or ambient, press, pulse [press vs pulse experiment]) at the start of the experiments. Tank (random effect: nested in Treatment) was included in the model as a random effect. Bold values denote significance.

## Supplementary material S4

## Photosynthetic pigments

Figure S4.1. Mean ( $\pm$ SE) chlorophyll $a$ (a), chlorophyll $c$ (b), and fucoxanthin (c) levels of Ecklonia radiata and Carpophyllum flexuosum after 30 days in each light treatment (ambient, low, critical, blackout) of the light intensity experiment. Bars not sharing the same letter are significantly different (pair-wise tests, $p<0.05 ; \mathrm{n}=10$ for each bar).

Figure S4.2. Mean ( $\pm \mathrm{SE}$ ) chlorophyll $a(\mathrm{a})$, chlorophyll $c(\mathrm{~b})$, and fucoxanthin (c) levels of Ecklonia radiata and Carpophyllum flexuosum after 30 days in each treatment (ambient, press, and pulse) of the press vs pulse experiment. Bars not sharing the same letter or light treatments not bracketed by the same horizontal line are significantly different (pair-wise tests, $p<0.05 ; \mathrm{n}=8$ for each bar).
