

Figure S1. From surveys in the Nisqually River delta, we converted data describing the presence and absence of eelgrass along transects into a polygon by using the aggregate points function in ArcGIS Pro.

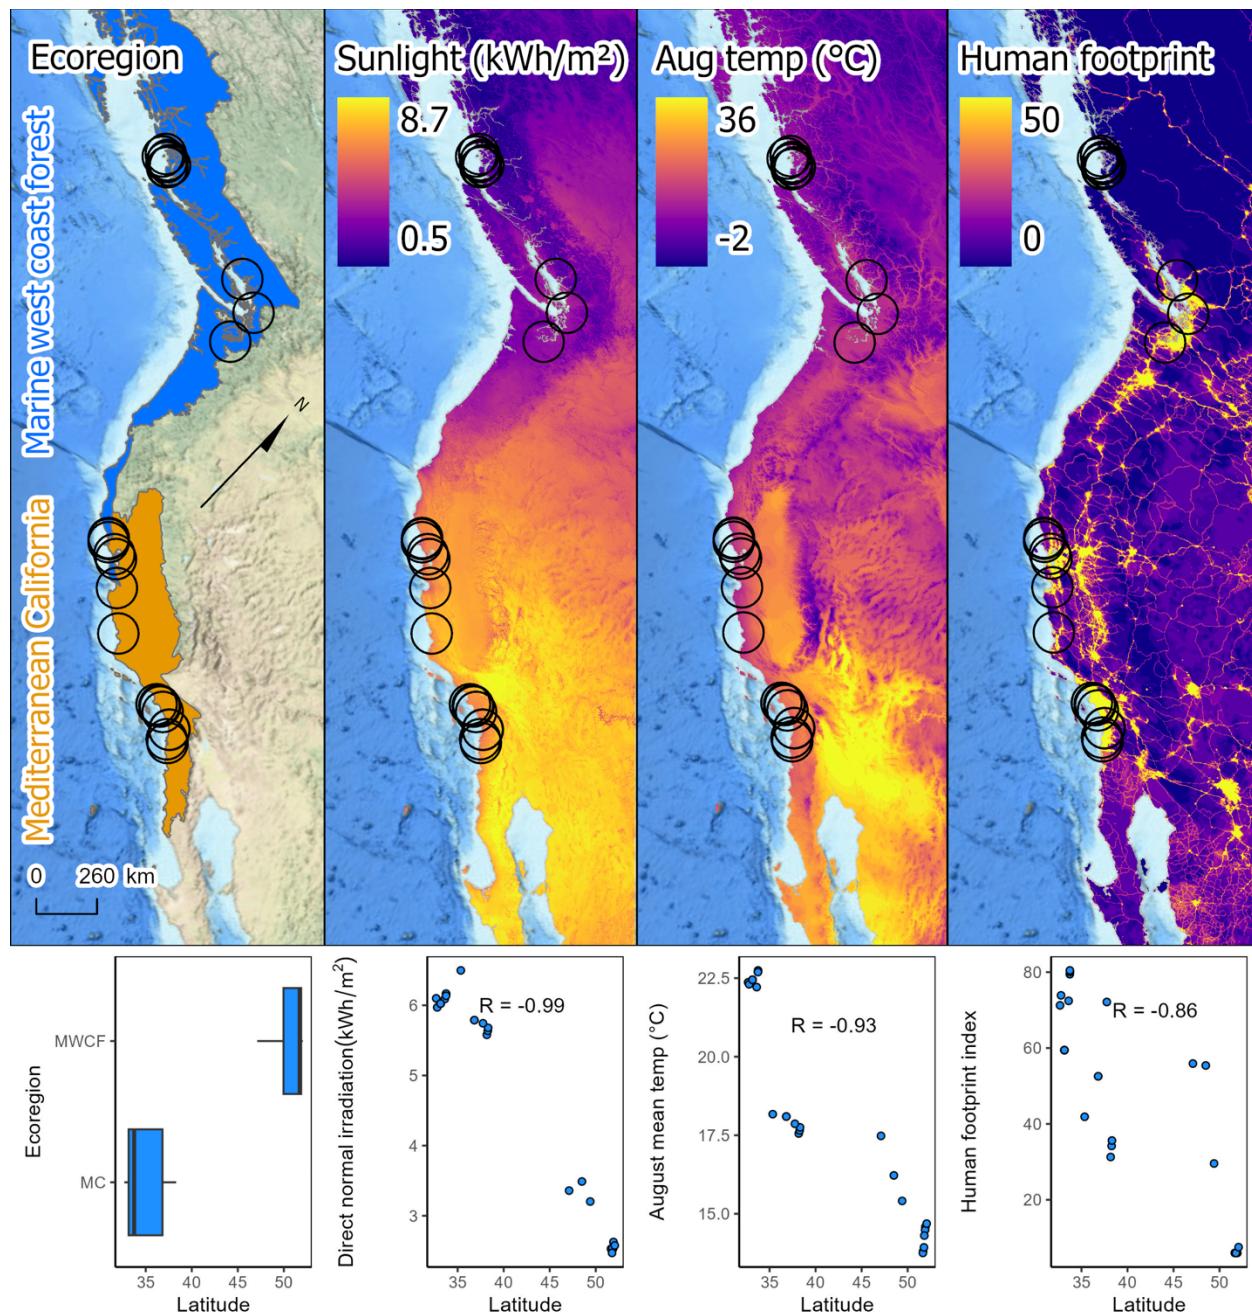

Figure S2. Relationships between sites' environmental variables and latitude, mapped above and plotted below. R: Pearson correlation coefficient. Ecoregion abbreviations: marine west coast forest (MWCF) and Mediterranean California (MC).

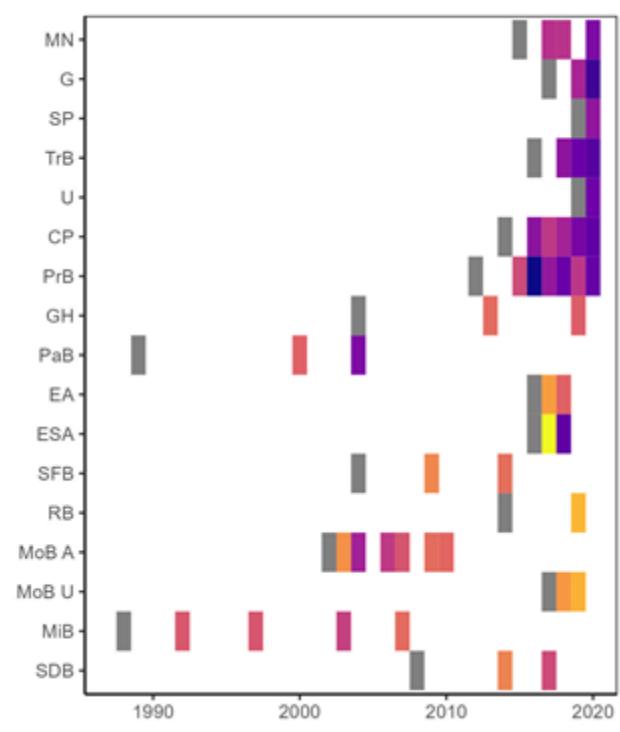

Figure S3. Figure 2, except all data are tier one. Additional abbreviations: Morro Bay UAV and Aerial (MoB U, MoB A).

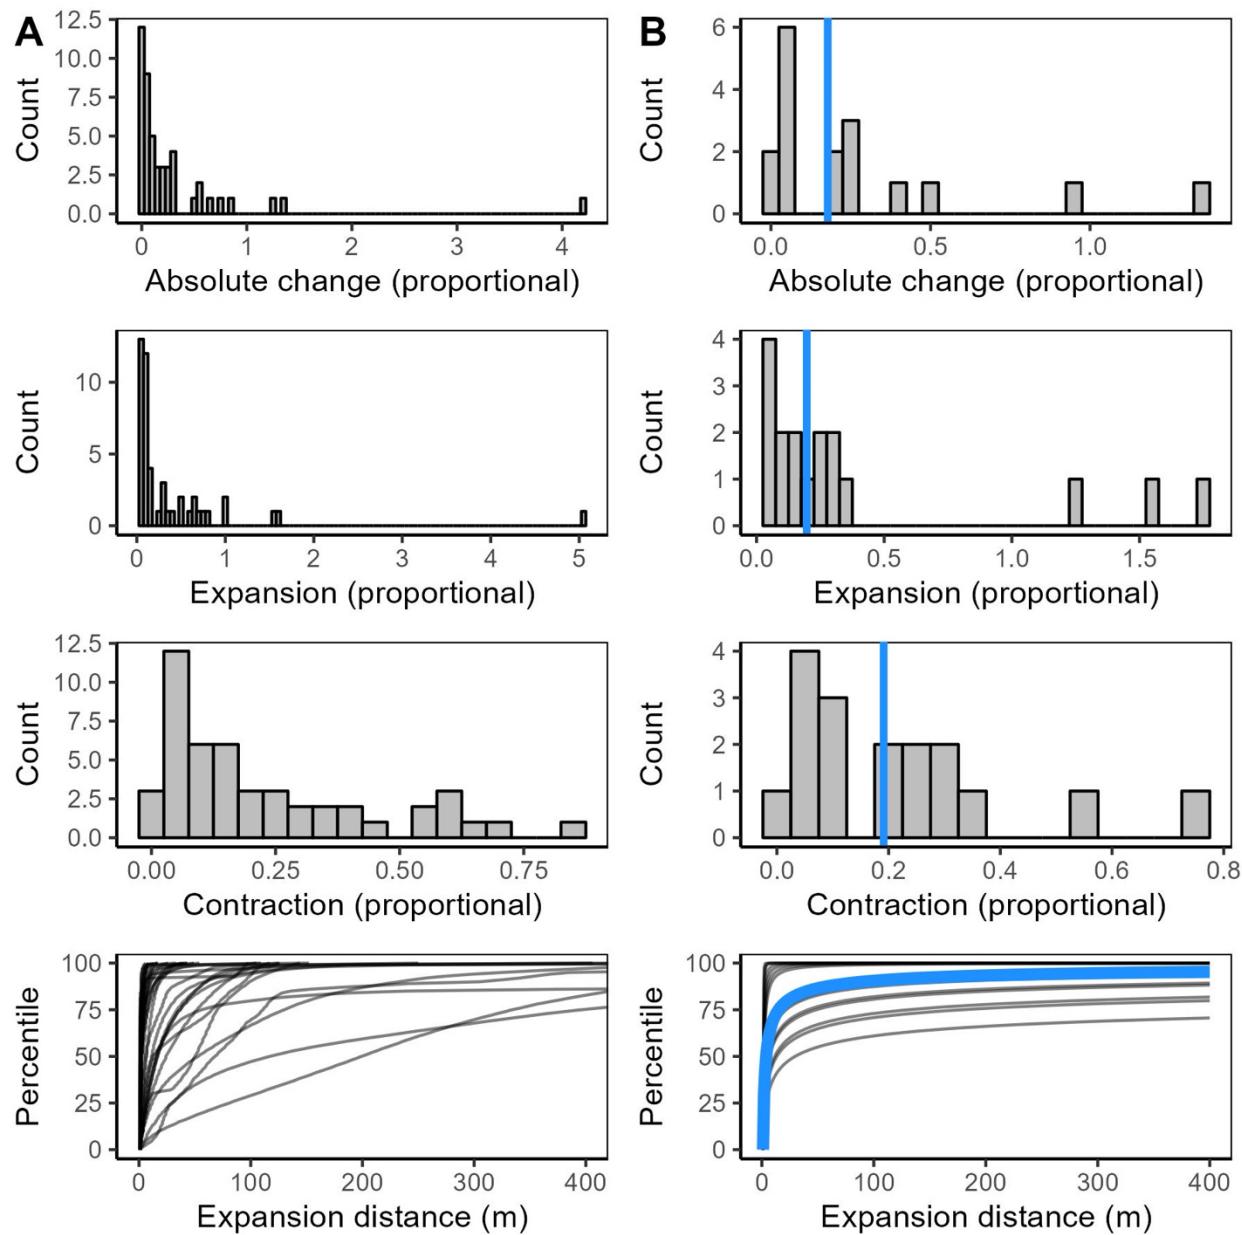

Figure S4. Figure 3, except all data are tier one and no models detected increased changes with increasing time between observations, so no model predictions are made using years between observations as a covariate. A: raw observations. B: model predictions.

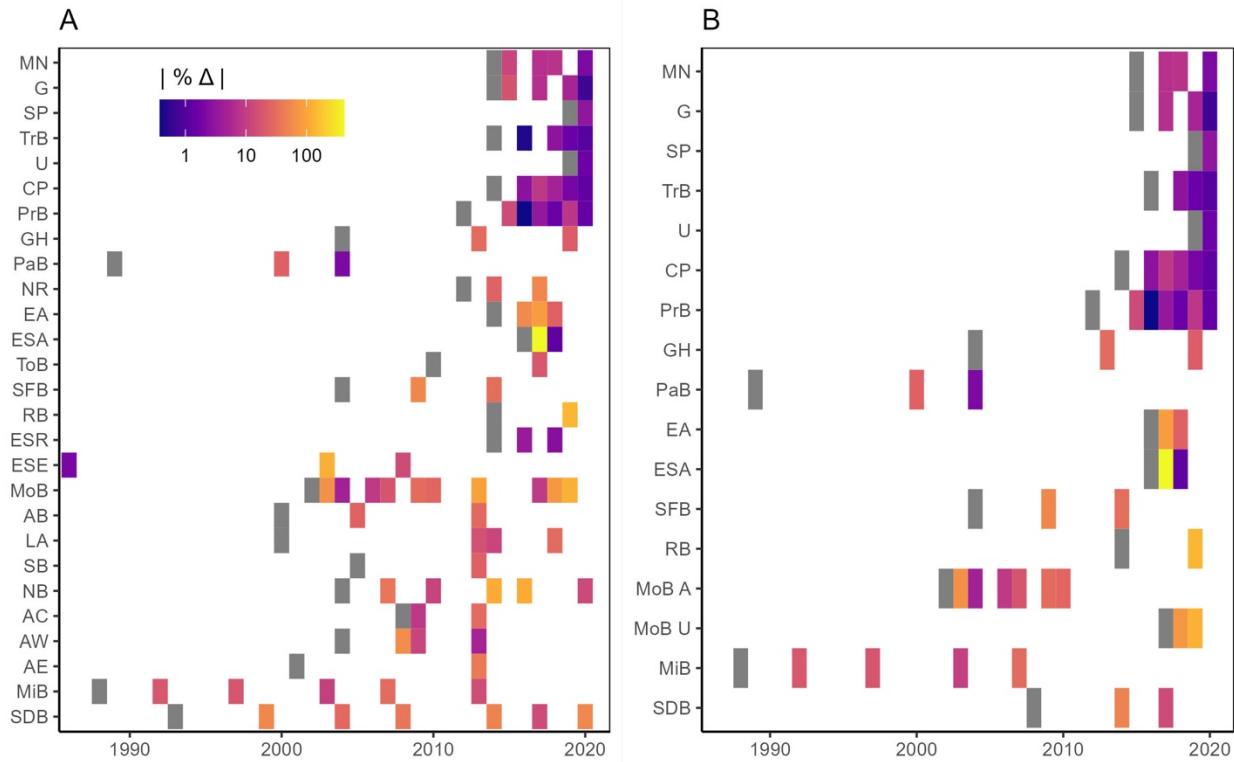

Figure S5. Figure 2, except percent change is divided by the length of time between observations describing all (A) and tier one (B) data.

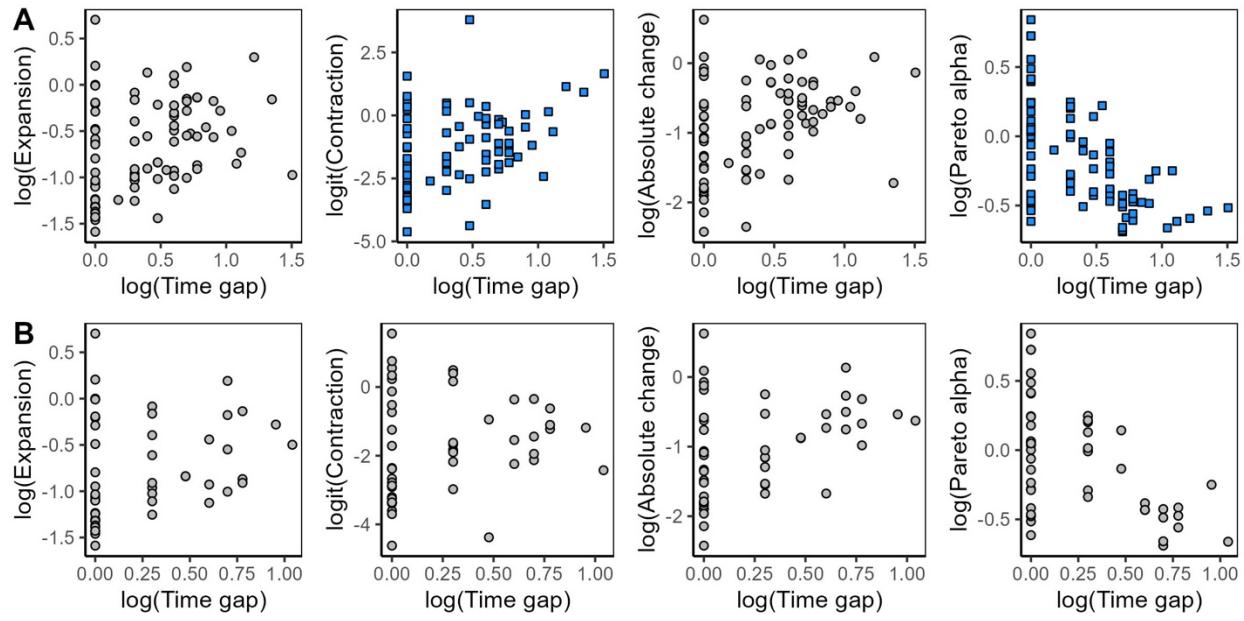

Figure S6. Examining for effects of time gaps between observations (in years) on eelgrass dynamics in all (A) and tier one (B) data. Blue squares indicate data supporting important relationships (determined via AICc) between eelgrass dynamics metrics and time gaps in models that also accounted for site effects.

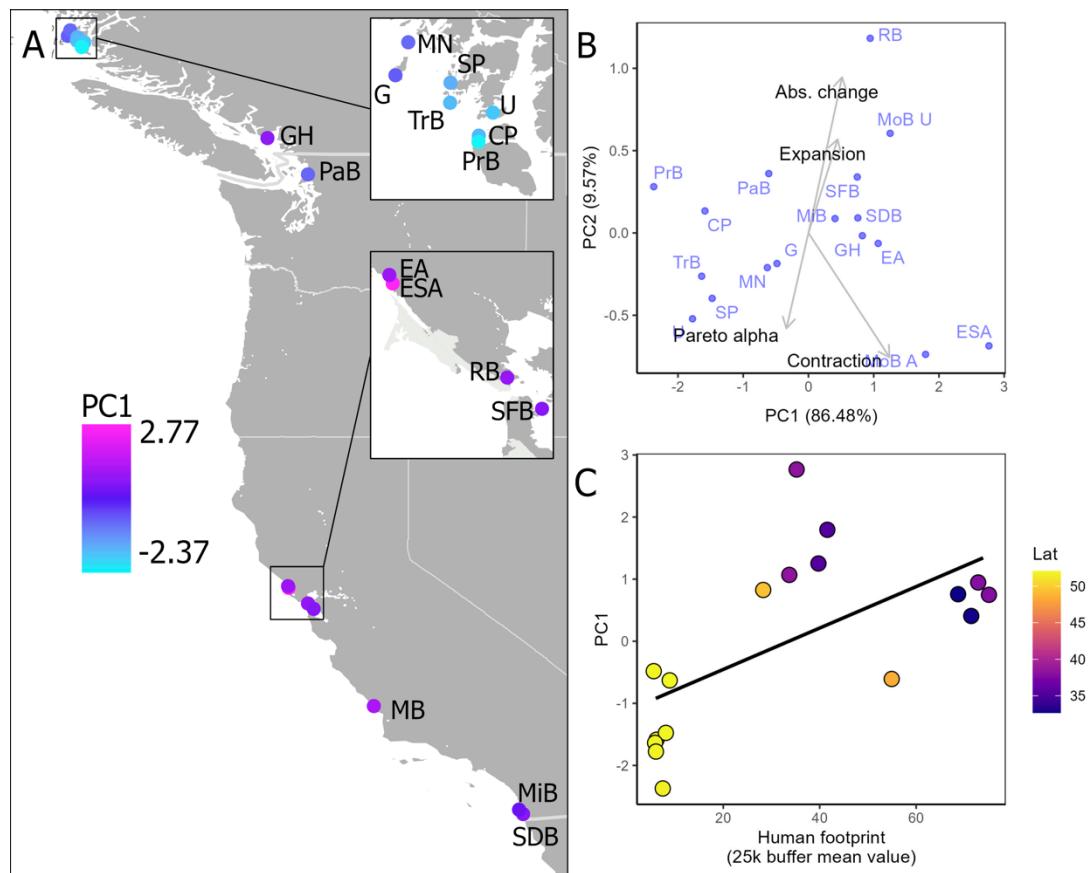

Figure S7. Figure 4, except all data are tier one.

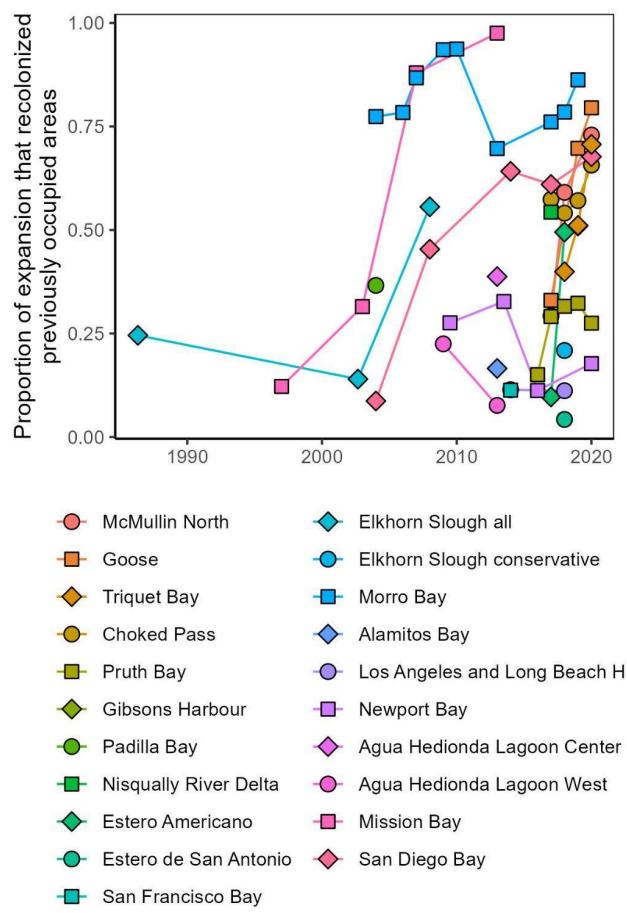

Figure S8. Figure 5, except all data are tier one.

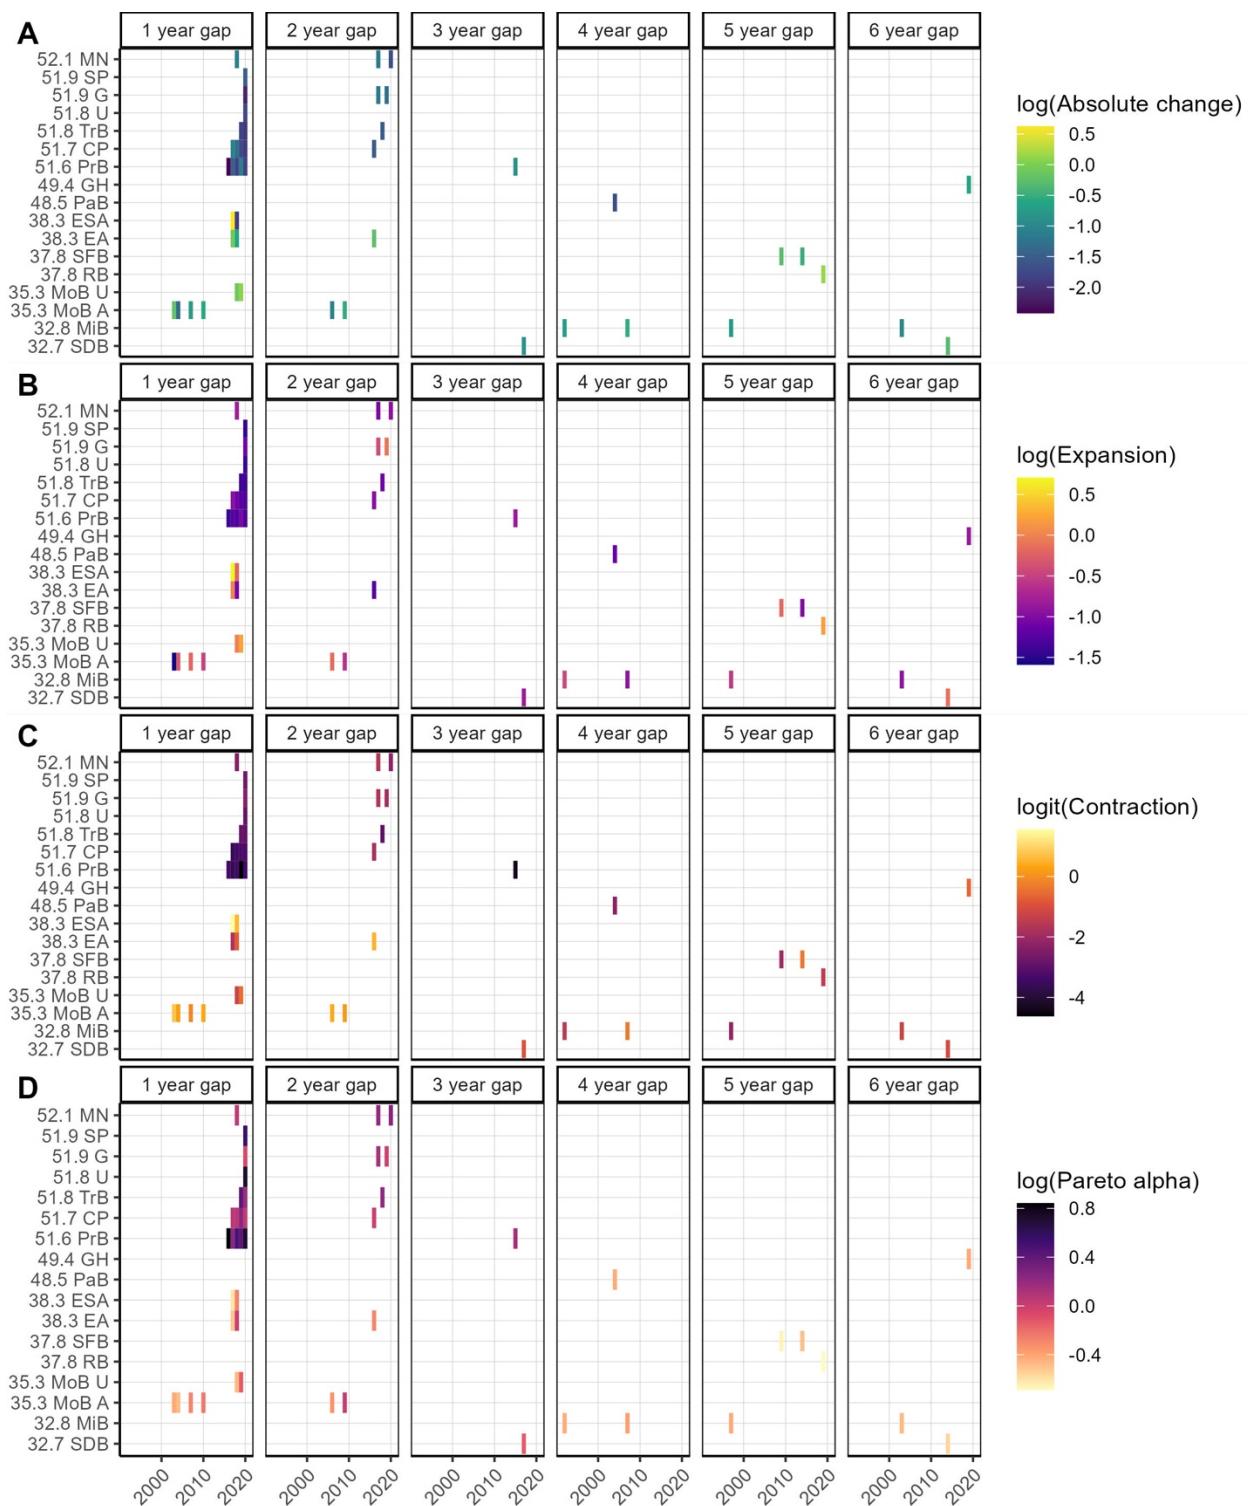

Figure S9. Eelgrass meadow dynamics metrics (rows A-D) compared among sites, faceted by the number of years between surveys. Numbers indicate latitude and site abbreviations are the same as in Figs. 2 and S3. The dark-light color ramp scheme for estimates of Pareto alphas has been reversed because higher values indicate less dramatic eelgrass meadow boundary shifts, whereas higher values for other metrics indicate greater changes. These are tier one data and observations made between more than 6 intervening years have been excluded because there were only singular instances of these time gaps, precluding comparisons among sites.

Table S1. Description of surveys used in this analysis. Tier one status is defined in terms of year pairs and is indexed in this table according to the second of the two years being compared. See Figure 5 in the main text for site locations.

Site	Year	Dates	Methods	Tier one
Agua Hedionda Lagoon Center	2008	11/26	Sonar, visual	NA
Agua Hedionda Lagoon Center	2009	4/22	Sonar, visual	no

Table S2. Results of ground-truthing used in some studies to test the accuracy of remote sensing eelgrass.

Site	Year	Technique	Results	Comments	Source
Mission Bay	1988	254 diver transects 91.44 m long to evaluate side-scan sonar mapping	94% accuracy in classification of eelgrass and positional placement	Accuracy highest in expansive meadows, lower in sparse patches	Merkel & Associates (2014)
Alamitos Bay	2013	200 drop camera points to evaluate side-scan sonar mapping	100% accuracy (23 true positives, 177 true negatives)		Merkel & Associates (2014)
British Columbia: Gwaii Haanas, Haida Gwaii, north coast; Hakai Lúxvbálís, central	2017	12 sites, with 39–184 ground truth points per site depending on site size. Towed video camera used to evaluate UAS	True positive accuracy: 97.6% 91.3% 84.2% 70.0%, 91.7% (dense, moderate, sparse, very sparse, unvegetated, respectively)	Eelgrass density categories: very sparse (5–20% cover), sparse (20–60% cover), moderately dense (60–80% cover), and very dense (80–100% cover)	Nahirnick et al. (2019)

coast; Gulf Islands, south-east coast; Broken Group, Pacific Rim National Park and south-west coast		mapping.
