

Vulnerability of the Critically Endangered leatherback turtle to fisheries bycatch in the eastern Pacific Ocean. I. A machine-learning species distribution model

Table S1. Performance metrics of the full models (all environmental and static variables) after being assessed by additional complementary hold-out cross-validation methods (included, for reference, results of the main K-fold cross-validation method) for the different presence-absence ratios (e.g., 50:50 presence to absence ratio = 50% presence data and 50% absence data in the model). El Nino/La Nina refers to the performance metrics obtained by the model after being trained with data outside El Nino or La Nina periods and tested against them. Similarly, inshore and offshore refer to the performance metrics obtained by the model after being trained with data from inshore or offshore (different limits of 90W and 100W explored) and tested against the other data.

| | | n.trees | Dev | AUC | TSS |
|-------------------|-----------------|---------|-------|------|------|
| 50:50 n = 2176 | K-fold | 3650 | 59.37 | 0.92 | 0.71 |

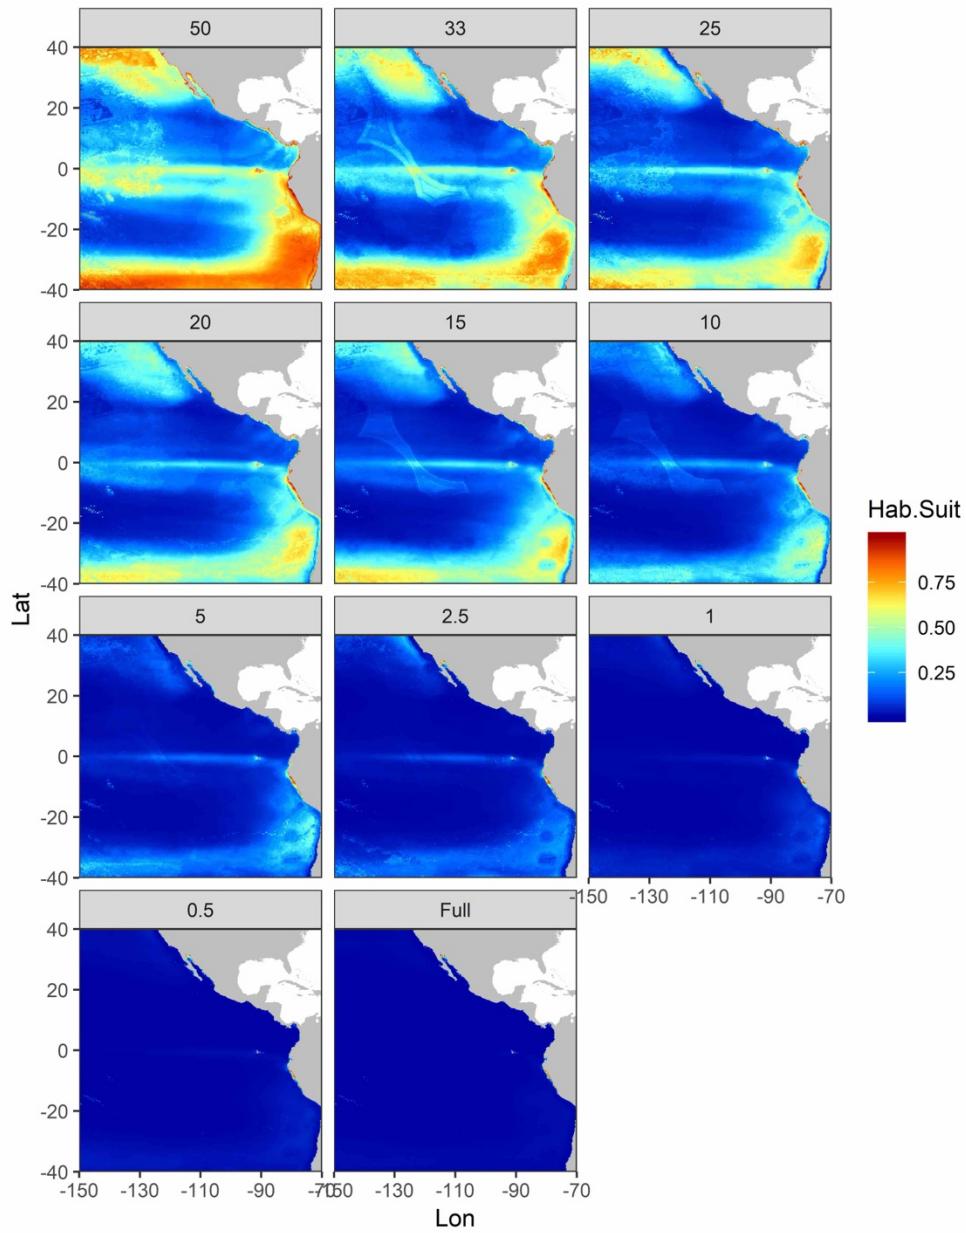

Figure S1. Model-specific predictions (averages for daily predictions for the period 2002–2020). The number on top of each panel denotes the ratio of presence to absences used to build the final model (e.g., 50 refers to a 50:50 presence to absence ratio, 33 to a 33:66 presence to absence ratio, etc.).

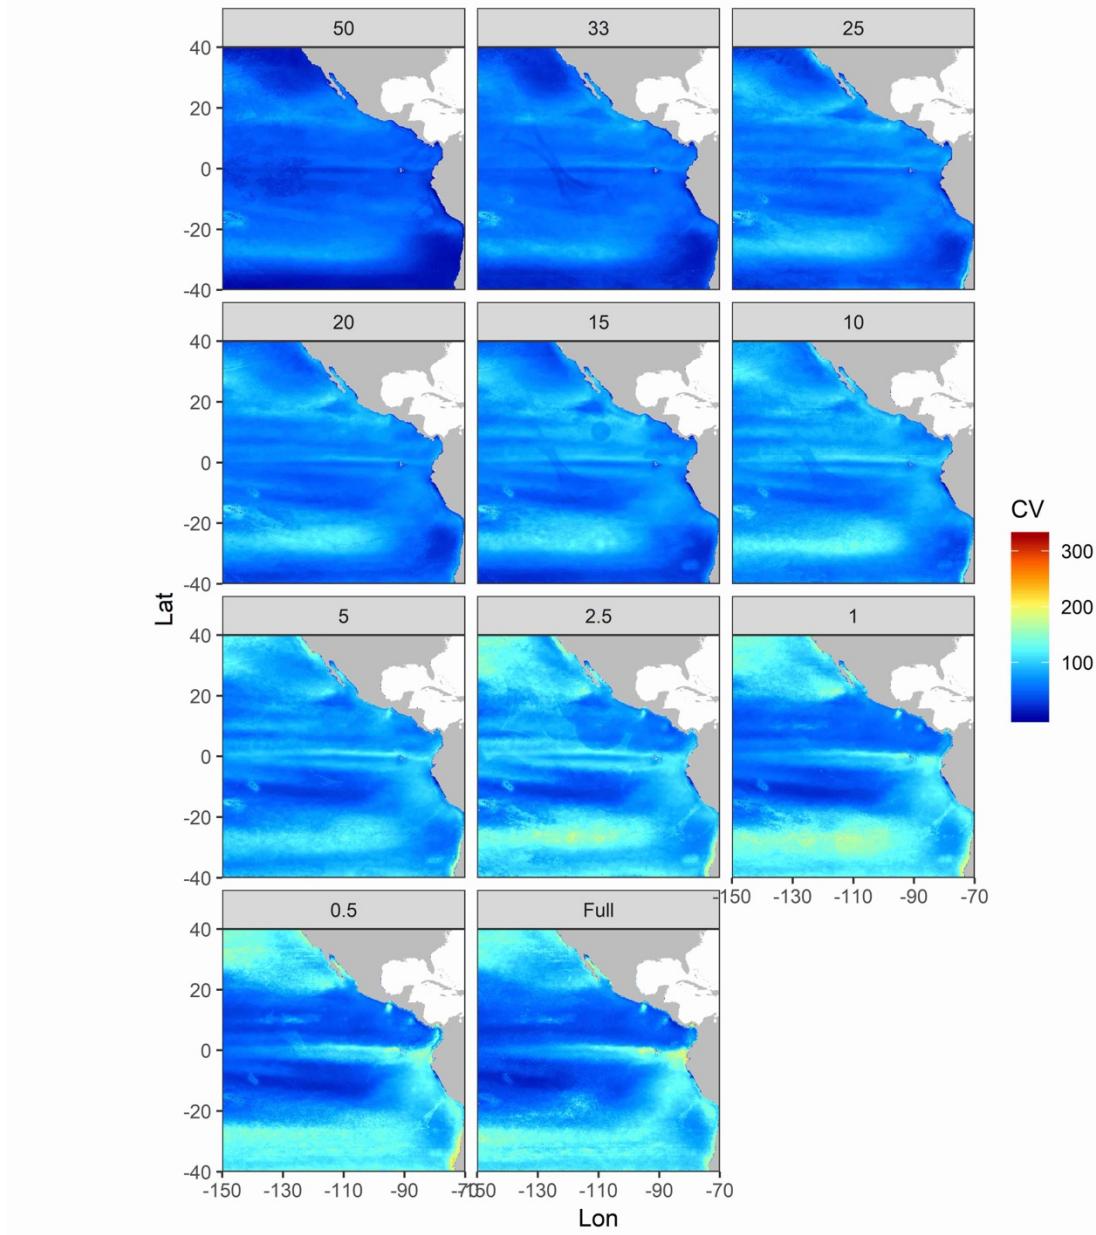

Figure S2. Model-specific coefficient of variation in predictions (averages for daily predictions for the period 2002–2020). The number on top of each panel denotes the ratio of presence to absences used to build the final model (e.g., 50 refers to a 50:50 presence to absence ratio, 33 to a 33:66 presence to absence ratio, etc.).

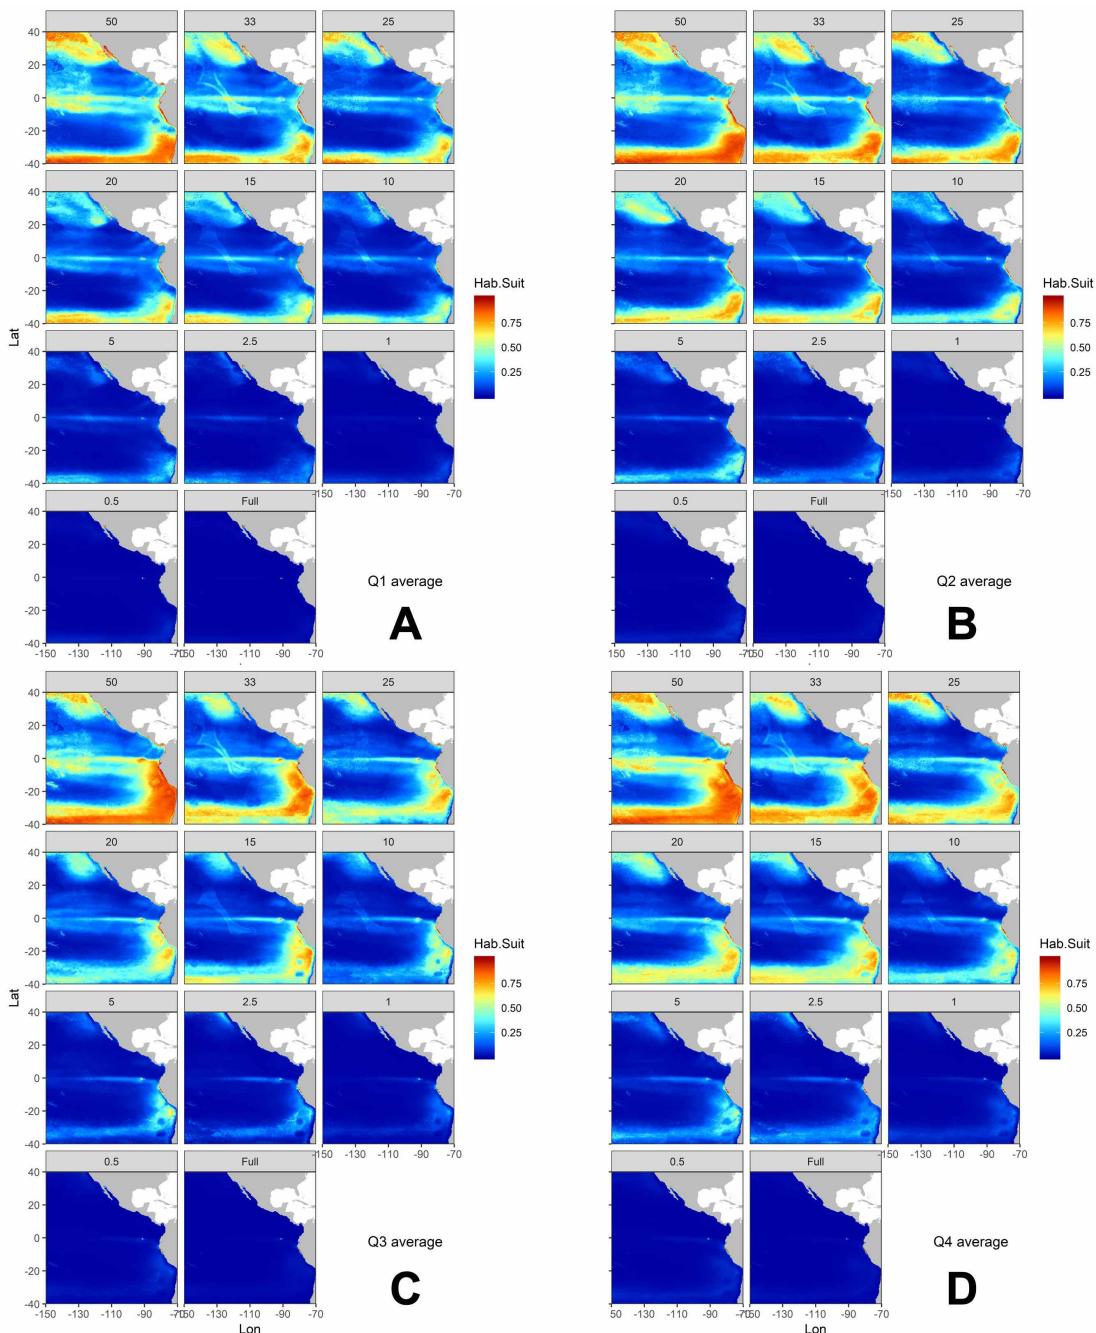

Figure S3. Model-specific predictions (averages for daily predictions for the period 2002–2020) for A) Q1, B) Q2, C) Q3 and D) Q4. The number on top of each panel denotes the ratio of presence to absences used to build the final model (e.g., 50 refers to a 50:50 presence to absence ratio, 33 to a 33:66 presence to absence ratio, etc.).

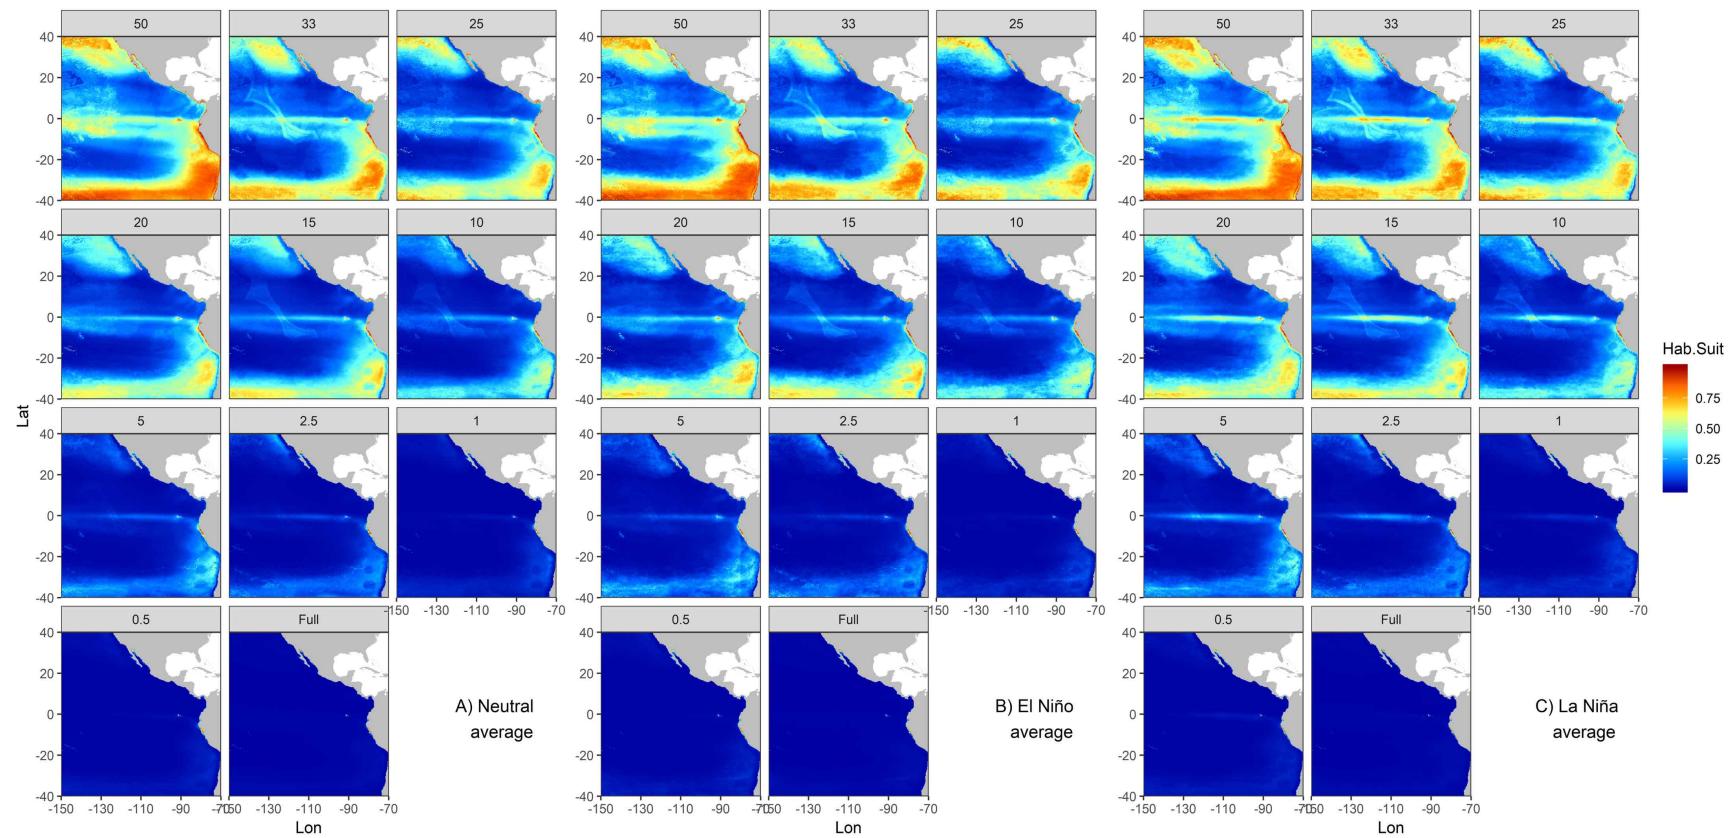

Figure S4. Model-specific predictions (averages for daily predictions for the period 2002–2020) for A) neutral years, B) El Niño years, and C) La Niña years. The number on top of each panel denotes the ratio of presence to absences used to build the final model (e.g., 50 refers to a 50:50 presence to absence ratio, 33 to a 33:66 presence to absence ratio, etc.).

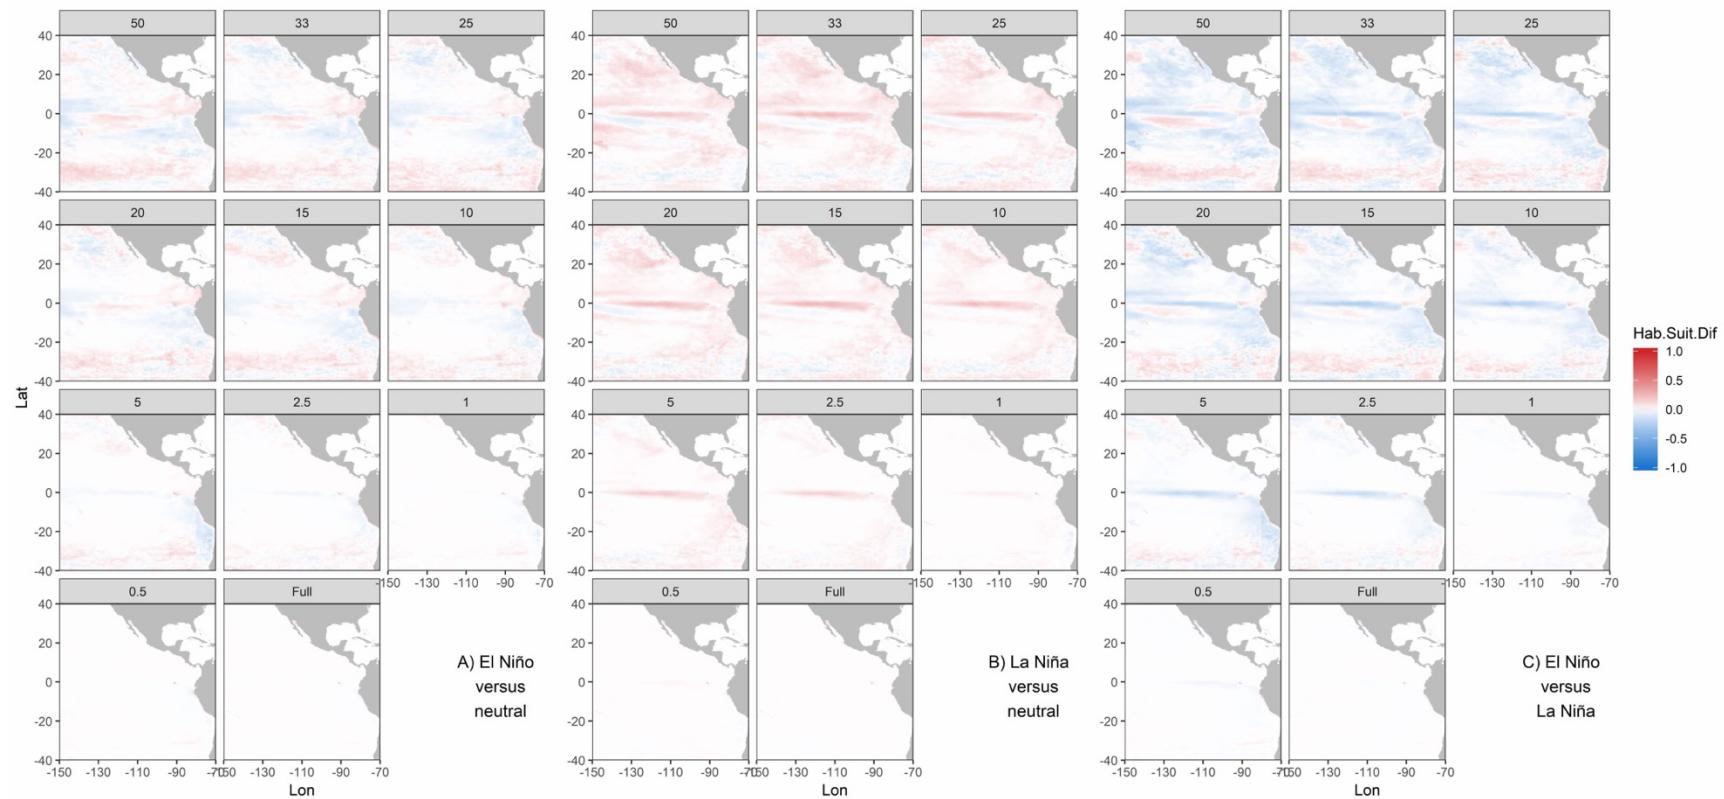

Figure S5. Relative differences in predicted leatherback habitat between A and B) El Niño and La Niña conditions compared to neutral years, and C) El Niño compared to La Niña. Red pixels represent net gain of predicted habitat while blue pixels represent net loss of predicted habitat of one phase relative to the other. The number on top of each panel denotes the ratio of presence to absences used to build the final model (e.g., 50 refers to a 50:50 presence to absence ratio, 33 to a 33:66 presence to absence ratio, etc.).

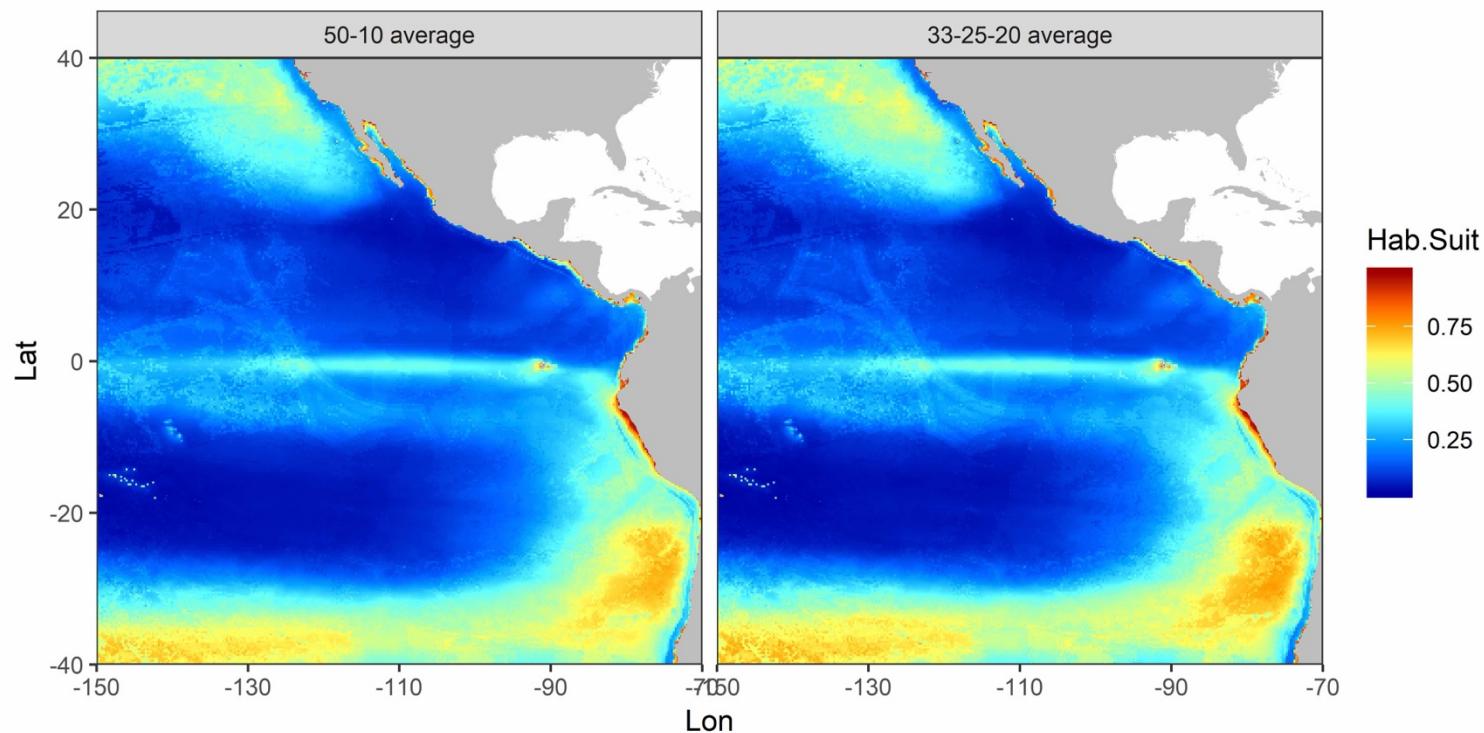

Figure S6. Average predictions from an ensemble of SDMs where the ratio of presence to absences were 50-10 (left panel) and 33-25-20 (right panel)

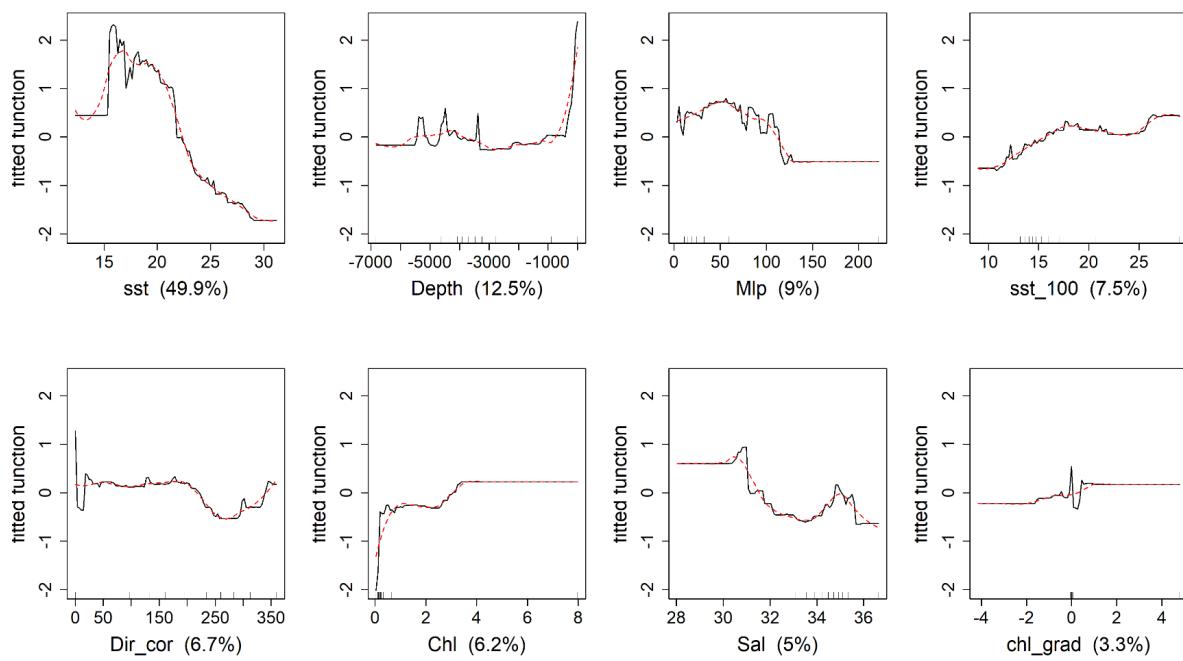

Figure S7. Partial dependence plots for leatherback turtle species distribution models (example of model with 25% of presences vs 75 absences – reference model)
